UNIT 1
IMPERATIVE PROGRAMMING
Types of computer programming languages

There are basically three types of computer programming languages, they are

- Low level programming languages
- Middle level programming languages
- High level programming languages
LOW LEVEL LANGUAGES

• These are machine dependent programming languages such as Binary (Machine code) and Assembly language.
• Since computer only understand the Binary language that means instructions in the form of 0’s and 1’s (Signals - that can be either High or Low), so these programming languages are the best way to give signals (Binary Instructions) to the computer directly.
• Machine Code (Binary Language) does not need any interpreter or compiler to convert language in any form because computer understands these signals directly.
• But, Assembly language needs to be converted in equivalent Binary code, so that computer can understand the instructions written in Assembly. Assembler is used to convert an assembly code to its equivalent Binary code.
• The codes written in such kind of languages are difficult to write, read, edit and understand; the programs are not portable to any other computer system.
MIDDLE LEVEL PROGRAMMING LANGUAGE

- Since, there is no such category of computer programming languages, but the programming languages that have features of low level and high level programming languages come under this category.

- Hence, we can say that the programming languages which have features of Low Level as well as High Level programming languages known as "Middle Level" programming language.

- C programming languages is the best example of Low Level Programming languages as it has features of low level and high level programming languages both.
High level programming languages

• These are the machine independent programming languages, which are easy to write, read, edit and understand.
• The languages like Java, .Net, Pascal, COBOL, C++, C, C# and other (which are very popular now to develop user end applications). These languages come under the high level programming language category.
• High level programming languages have some special keywords, functions and class libraries by using them we can easily build a program for the computer.
• Computer does not understand program written in such languages directly, as I have written above that computer understands only Machine code. So, here programming translators are required to convert a high level program to its equivalent Machine code.
• Programming translators such as Compilers and Interpreters are the system software’s which converts a program written in particular programming languages to its equivalent Machine code.
FEATURES OF HIGH LEVEL PROGRAMMING LANGUAGES

• The programs are written in High Level programming languages and are independent that means a program written on a system can be run on another system.

• Easy to understand - Since these programming languages have keywords, functions, class libraries (which are similar to English words) we can easily understand the meaning of particular term related to that programming language.

• Easy to code, read and edit - The programs written in High Level programming languages are easy to code, read and edit. Even we can edit programs written by other programmers easily by having little knowledge of that programming language.

• Since, High Level language programs are slower than Low level language programs; still these programming languages are popular to develop User End Applications.

Compiled by Ms. Prajakta Joshi
IMPERATIVE PROGRAMMING

• **Imperative programming** is a paradigm of computer programming in which the program describes a sequence of steps that change the state of the computer.

• Unlike declarative programming, which describes "what" a program should accomplish, imperative programming explicitly tells the computer "how" to accomplish it.

• Programs written this way often compile to binary executables that run more efficiently since all CPU instructions are themselves imperative statements.

• To make programs simpler for a human to read and write, imperative statements can be grouped into sections known as code blocks.
FEATURES OF IP

• **Procedural programming** is a type of imperative programming in which the program is built from one or more procedures (also termed subroutines).

• To make programs simpler for a human to read and write, imperative statements can be grouped into sections known as **code blocks**.
HISTORY OF IP

• Earlier computers had fixed programs: they were hardwired to do one thing.
• Sometimes external programs were implemented with paper tape or by setting switches.
• First imperative languages: assembly languages
• 1954-1955: Fortran (FORmula TRANslator)
  John Backus developed for IBM 704
• Late 1950's: Algol (ALGOarithmic Language)
• 1958: Cobol (COmmon Business Oriented Language) Developed by a government committee; Grace Hopper very influential.

• The earliest imperative languages were the machine languages of the original computers.
• In these languages, instructions were very simple, which made hardware implementation easier, but hindered the creation of complex programs.
• **C programming language** was developed in 1972 by Dennis Ritchie at Bell laboratories of AT&T (American Telephone & Telegraph), located in the U.S.A.

• **Dennis Ritchie** is known as the **founder of the c language**.

• It was developed to overcome the problems of previous languages such as B, BCPL, etc.

• Initially, C language was developed to be used in **UNIX operating system**. It inherits many features of previous languages such as B and BCPL.

• Let's see the programming languages that were developed before C language.
## EVOLUTION OF PROGRAMMING MODEL

IMPERATIVE PROGRAMMING

• **Advantage:**
  • Very simple to implement
  • Better encapsulation
  • Bugs free code
  • It contains loops, variables etc.

• **Disadvantage:**
  • Complex problem cannot be solved
  • Less efficient and less productive
  • Parallel programming is not possible

Compiled by Ms. Prajakta Joshi
ALGORITHM

- In programming, algorithm is a set of well defined instructions in sequence to solve the problem.
- The word “algorithm” relates to the name of the mathematician Al-Khowarizmi, which means a procedure or a technique.
- Software Engineer commonly uses an algorithm for planning and solving the problems.
- An algorithm is a sequence of steps to solve a particular problem or algorithm is an ordered set of unambiguous steps that produces a result and terminates in a finite time.

Compiled by Ms. Prajakta Joshi
QUALITIES OF A GOOD ALGORITHM

• Input and output should be defined precisely.
• Each steps in algorithm should be clear and unambiguous.
• Algorithm should be most effective among many different ways to solve a problem.
• An algorithm shouldn't have computer code. Instead, the algorithm should be written in such a way that, it can be used in similar programming languages
ADVANTAGES OF ALGORITHM

• It is a step-wise representation of a solution to a given problem, which makes it easy to understand.
• An algorithm uses a definite procedure.
• It is not dependent on any programming language, so it is easy to understand for anyone even without programming knowledge.
• Every step in an algorithm has its own logical sequence so it is easy to debug.
HOW TO WRITE ALGORITHMS

• Step 1 Define your algorithms input: Many algorithms take in data to be processed, e.g. to calculate the area of rectangle input may be the rectangle height and rectangle width.

• Step 2 Define the variables: Algorithm's variables allow you to use it for more than one place. We can define two variables for rectangle height and rectangle width as HEIGHT and WIDTH (or H & W).

• Step 3 Outline the algorithm's operations: Use input variable for computation purpose, e.g. to find area of rectangle multiply the HEIGHT and WIDTH variable and store the value in new variable (say) AREA. An algorithm's operations can take the form of multiple steps and even branch, depending on the value of the input variables.

• Step 4 Output the results of your algorithm's operations: In case of area of rectangle output will be the value stored in variable AREA, if the input variables described a rectangle with a HEIGHT of 2 and a WIDTH of 3, the algorithm would output the value of 6.
WRITE AN ALGORITHM TO ADD TWO NUMBERS ENTERED BY USER.
WRITE AN ALGORITHM TO ADD TWO NUMBERS ENTERED BY USER.

• Step 1: Start
• Step 2: Declare variables num1, num2 and sum.
• Step 3: Read values num1 and num2.
• Step 4: Add num1 and num2 and assign the result to sum.
  sum ← num1 + num2
• Step 5: Display sum
• Step 6: Stop
ALGORITHM FOR AREA OF RECTANGLE

• START
• Input Length of Rectangle as \( L \)
• Input Breadth of Rectangle as \( B \)
• Calculate \( \text{Area} = L \times B \)
• Print Value of \( \text{Area} \)
• END / STOP

Compiled by Ms. Prajakta Joshi
PSEUDOCODE

- Artificial, informal language used to develop algorithms
- Similar to everyday English
- Not executed on computers
  - Used to think out program before coding
    - Easy to convert into C++ program
  - Only executable statements
  - No need to declare variables
  - It’s simply an implementation of an algorithm in the form of annotations and informative text written in plain English. It has no syntax like any of the programming language and thus can’t be compiled or interpreted by the computer.
ADVANTAGES OF PSEUDOCODE

• Improves the readability of any approach. It’s one of the best approaches to start implementation of an algorithm.

• Acts as a bridge between the program and the algorithm or flowchart. Also works as a rough documentation, so the program of one developer can be understood easily when a pseudo code is written out. In industries, the approach of documentation is essential. And that’s where a pseudo-code proves vital.

• The main goal of a pseudo code is to explain what exactly each line of a program should do, hence making the code construction phase easier for the programmer.
FLOWCHART

• A flowchart is a diagrammatic representation that illustrates the sequence of operations to be performed to get the solution to a problem.
• It can be seen from the definition that a flow always accompanies with business or transaction.
• Not all of the flows, however, are appropriate to be expressed by flowcharts, unless these flows are based on some fixed routines and stable links.
FLOWCHART SYMBOLS

- Terminator
  The terminator symbol represents the starting or ending point of the system.
- Process
  A box indicates some particular operation.
- Document
  This represents a printout, such as a document or a report.

Compiled by Ms. Prajakta Joshi
• **Decision**

A diamond represents a decision or branching point. Lines coming out from the diamond indicate different possible situations, leading to different sub-processes.

• **Data**

It represents information entering or leaving the system. An input might be an order from a customer. An output can be a product to be delivered.

• **On-Page Reference**

This symbol would contain a letter inside. It indicates that the flow continues on a matching symbol containing the same letter somewhere else on the same page.
• Off-Page Reference
This symbol would contain a letter inside. It indicates that the flow continues on a matching symbol containing the same letter somewhere else on a different page.
• Delay or Bottleneck
Identifies a delay or a bottleneck.
• Flow
• Lines represent flow of the sequence and direction of a process.
DRAW A FLOWCHART TO ADD TWO NUMBERS ENTERED BY USER.
DRAW FLOWCHART TO FIND THE LARGEST AMONG THREE DIFFERENT NUMBERS ENTERED BY USER.
• Actually, the computer cannot understand your program directly given in the text format, so we need to convert this program in a binary format, which can be understood by the computer.

• The conversion from text program to binary file is done by another software called Compiler and this process of conversion from text formatted program to binary format file is called program compilation. Finally, you can execute binary file to perform the programmed task.

• Advantages of Compiler
  • A compiler runs much faster.
  • The program can be distributed to many people who don’t have compilers since a compiler is not needed after compiling occurs.
  • A compiler is stored as an executable file.
COMPILED
In **programming**, **sentinel value** is a special **value** that is used to **terminate** a loop. The **sentinel value** typically is chosen so as to not be a legitimate data **value** that the loop will encounter and attempt to perform with.

The sentinel value typically is chosen so as to not be a legitimate data value that the loop will encounter and attempt to perform with. For example, in a loop **algorithm** that computes non-negative integers, the value "-1" can be set as the sentinel value as the computation will never encounter that value as a legitimate processing output.
We just discussed about compilers and the compilation process. Compilers are required in case you are going to write your program in a programming language that needs to be compiled into binary format before its execution.

There are other programming languages such as Python, PHP, and Perl, which do not need any compilation into binary format, rather an interpreter can be used to read such programs line by line and execute them directly without any further conversion.

Advantage of an interpreter:
- It immediately displays feedback when it finds a syntax error.
- The programmer can correct any errors or debug the code before the interpreter evaluates the next line.

Disadvantages:
- Interpreted programs do not run as fast as compiled programs because the program must be translated to machine language each time it is executed.
INTERPRETER

Compiled by Ms. Prajakta Joshi
# PROGRAM FOR “HELLO WORLD”

- `#include <stdio.h>`
- `int main()`
  -`
    // printf() displays the string inside quotation
    printf("Hello, World!");
    return 0;
  `
• The `#include <stdio.h>` is a preprocessor command. This command tells the compiler to include the contents of `stdio.h` (standard input and output) file in the program. The `stdio.h` file contains functions such as `scanf()` and `printf()` to take input and display output respectively. If you use `printf()` function without writing `#include <stdio.h>`, the program will not be compiled.

• The execution of a C program starts from the `main()` function.

• The `printf()` is a library function to send formatted output to the screen. In this program, the `printf()` displays Hello, World! text on the screen.

• The `return 0;` statement is the "Exit status" of the program. In simple terms, the program ends with this statement.
#include<stdio.h>

int main()
{
    int a, b, c;

    printf("Enter two numbers to add\n");
    scanf("%d%d", &a, &b);

    c = a + b;

    printf("Sum of the numbers = %d\n", c);

    return 0;
}
PROGRAM DEVELOPMENT LIFE CYCLE

1. Problem Definition
2. Problem Analysis
3. Algorithm Development
4. Coding & Documentation
5. Testing & Debugging
6. Maintenance

Program Development Life Cycle

Compiled by Ms. Prajakta Joshi
Program Development Cycle

- Program development cycle steps:
  - Problem definition.
  - Problem analysis (understanding).
  - Algorithm development:
    - Ways for algorithm representation:
      - Human language
      - Pseudocode.
      - Flowcharts (also called UML activity diagram).
  - Coding.
  - Execution and testing.
  - Maintenance.

- Recall that such cycle and all the techniques presented in this lecture are the same for any programming language you want to use not only for C++.

The Hashemite University
Problem Definition
• needed output
• available input
• definition of how to transform available input into needed output (or processing requirements).

Analyze Problem
• Review the program specifications package
• Meet with the systems analyst and users
• Identify the program’s input, output, and processing requirements (IPO)
- **Design Programs**
  - Group the program activities into modules
  - Devise a solution algorithm for each module
  - Test the solution algorithms
  - Top-down design
  - Identify the major activity of the program
  - Break down the original set of program specifications into smaller, more manageable sections which makes it easier to solve that the original one.
  - Continue to break down subroutines into modules which is a section of a program dedicated to performing a single function.
  - Hierarchy Chart or Top-Down Charts

Compiled by Ms. Prajakta Joshi
Developing an Algorithm

- Programmers begin solving a problem by developing an algorithm.
- An algorithm is a step-by-step description of how to arrive at a solution. You can think of an algorithm as a recipe or a how-to sheet.

Program Code

- Writing the actual program is called coding.
- This is where the programmer translates the logic of the pseudocode into actual program code.
- Programs should be written on paper first.
- A good program is one that is:
  - Reliable
  - Works under most conditions
  - Catches obvious and common input errors.
Test Programs

Types of errors

- Syntax errors – occurs when the code violates the syntax, or grammar, of the programming language.
  - Misspelling a command
  - Leaving out required punctuation
  - Typing command words out of order
- Logic errors a flaw in the design that generates inaccurate results.

All programs must be tested for errors. This is a process known as debugging.

There are two types of errors that must be eliminated from a program before it can be used in a real-time computing environment. They are:

- Syntax Errors
- Logic Errors
• **Debugging**
  • There are several methods of debugging a program. They include:
    • Desk checking
    • Manual testing with sample data
    • Testing sample data on the computer
    • Testing by a select group of potential users.

• **Maintain Programs**
  • Correct errors
  • Add enhancements
    • Fix errors
    • Modify or expand the program
• **Program Maintenance**

• Programming maintenance activities fall into two categories: operations and changing needs.

• **Operations** - Locating and correcting operational errors and standardizing software.

• **Changing Needs** - Programs may need to be modified for a variety of reasons. For example new tax laws, new company policies.
C PROGRAM STRUCTURE

- Documentations (Documentation Section)
- Preprocessor Statements (Link Section)
- Global Declarations (Definition Section)
- The main() function
  - Local Declarations
  - Program Statements & Expressions
- User Defined Functions

Compiled by Ms. Prajakta Joshi
COMPILATION AND EXECUTION OF A PROGRAM

• Let's try to understand the flow of above program by the figure given below.
• 1) C program (source code) is sent to preprocessor first. The preprocessor is responsible to convert preprocessor directives into their respective values. The preprocessor generates an expanded source code.
• 2) Expanded source code is sent to compiler which compiles the code and converts it into assembly code.
• 3) The assembly code is sent to assembler which assembles the code and converts it into object code. Now a simple.obj file is generated.
• 4) The object code is sent to linker which links it to the library such as header files. Then it is converted into executable code. A simple.exe file is generated.
• 5) The executable code is sent to loader which loads it into memory and then it is executed. After execution, output is sent to console

IDENTIFIERS

- Identifiers are user-defined names of variables, functions and arrays. It comprises of combination of letters and digits. In C Programming, while declaring identifiers, certain rules have to be followed viz.
- It must begin with an alphabet or an underscore and not digits.
- It must contain only alphabets, digits or underscore.
- A keyword cannot be used as an identifier.
- Must not contain white space.
- Only first 31 characters are significant.
- Let us again consider an example
- `int age1; float height_in_feet;`
DATA TYPES

• Primary Data Types
• Derived Data Types
• User Defined Data Types

Compiled by Ms. Prajakta Joshi
## PRIMARY DATA TYPES

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td>As the name suggests, it holds no value and is generally used for specifying the type of function or what it returns. If the function has a void type, it means that the function will not return any value.</td>
</tr>
<tr>
<td>int</td>
<td>Used to denote an integer type.</td>
</tr>
<tr>
<td>char</td>
<td>Used to denote a character type.</td>
</tr>
<tr>
<td>float, double</td>
<td>Used to denote a floating point type.</td>
</tr>
<tr>
<td>int *, float *, char *</td>
<td>Used to denote a pointer type.</td>
</tr>
</tbody>
</table>
# DERIVED DATA TYPES

<table>
<thead>
<tr>
<th>Data Types</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arrays</td>
<td>Arrays are sequences of data items having homogeneous values. They have adjacent memory locations to store values.</td>
</tr>
<tr>
<td>Reference(s)</td>
<td>Function pointers allow referencing functions with a particular signature.</td>
</tr>
<tr>
<td>Pointers</td>
<td>These are powerful C features which are used to access the memory and deal with their addresses.</td>
</tr>
</tbody>
</table>
# USER DEFINED DATA TYPES

<table>
<thead>
<tr>
<th>Data Types</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Structure</strong></td>
<td>It is a package of variables of different types under a single name. This is done to handle data efficiently. &quot;struct&quot; keyword is used to define a structure.</td>
</tr>
<tr>
<td><strong>Union</strong></td>
<td>These allow storing various data types in the same memory location. Programmers can define a union with different members, but only a single member can contain a value at a given time. It is used for</td>
</tr>
<tr>
<td><strong>Enum</strong></td>
<td>Enumeration is a special data type that consists of integral constants, and each of them is assigned with a specific name. &quot;enum&quot; keyword is used to define the enumerated data type.</td>
</tr>
</tbody>
</table>
• C Constants is the most fundamental and essential part of the C programming language. Constants in C are the fixed values that are used in a program, and its value remains the same during the entire execution of the program.
• Constants are also called literals.
• Constants can be any of the data types.
• It is considered best practice to define constants using only upper-case names.
IF CONDITIONAL STATEMENT
IF....ELSE STATEMENT
## ARITHMETIC OPERATORS

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Adds two operands.</td>
<td>A + B = 30</td>
</tr>
<tr>
<td>−</td>
<td>Subtracts second operand from the first.</td>
<td>A − B = -10</td>
</tr>
<tr>
<td>*</td>
<td>Multiplies both operands.</td>
<td>A * B = 200</td>
</tr>
<tr>
<td>/</td>
<td>Divides numerator by denominator.</td>
<td>B / A = 2</td>

<tr>
<td>--</td>
<td>Decrement operator decreases the integer value by one.</td>
<td>A-- = 9</td>
</tr>
</tbody>
</table>

Compiled by Ms. Prajakta Joshi
```c
#include <stdio.h>

main()
{
    int a = 21; int b = 10; int c;
    c = a + b;
    printf("Line 1 - Value of c is %d\n", c);
    c = a - b;
    printf("Line 2 - Value of c is %d\n", c);
    c = a * b;
    printf("Line 3 - Value of c is %d\n", c);
    c = a / b;
    printf("Line 4 - Value of c is %d\n", c);
    c = a % b;
    printf("Line 5 - Value of c is %d\n", c);
}
```
**UNARY OPERATORS IN C**

- **Unary operator**: are operators that act upon a single operand to produce a new value.
- **Types of unary operators**:
  - unary minus (-)
  - increment (++)
  - decrement (--)
  - NOT (!)
  - Addressof operator (&)
  - sizeof ()
#include <stdio.h>

int main()
{
    int a = 10, b = 100;
    float c = 10.5, d = 100.5;
    printf("++a = %d \n", ++a);
    printf("--b = %d \n", --b);
    printf("++c = %f \n", ++c);
    printf("--d = %f \n", --d);
    return 0;
}
#include <stdio.h>

int main()
{
    int a;
    float b;
    double c;
    char d;

    printf("Size of int=\%lu bytes\n",sizeof(a));
    printf("Size of float=\%lu bytes\n",sizeof(b));
    printf("Size of double=\%lu bytes\n",sizeof(c));
    printf("Size of char=\%lu byte\n",sizeof(d));
    return 0;
}
## RELATIONAL OPERATORS

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>==</td>
<td>Checks if the values of two operands are equal or not. If yes, then the condition becomes true.</td>
<td>(A == B) is not true.</td>

<tr>
<td>!=</td>
<td>Checks if the values of two operands are equal or not. If the values are not equal, then the condition becomes true.</td>
<td>(A != B) is true.</td>
</tr>
<tr>
<td>&gt;</td>
<td>Checks if the value of left operand is greater than the value of right operand. If yes, then the condition becomes true.</td>
<td>(A &gt; B) is not true.</td>
</tr>
<tr>
<td>&lt;</td>
<td>Checks if the value of left operand is less than the value of right operand. If yes, then the condition becomes true.</td>
<td>(A &lt; B) is true.</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Checks if the value of left operand is greater than or equal to the value of right operand. If yes, then the condition becomes true.</td>
<td>(A &gt;= B) is not true.</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Checks if the value of left operand is less than or equal to the value of right operand. If yes, then the condition becomes true.</td>
<td>(A &lt;= B) is true.</td>
</tr>
</tbody>
</table>
#include <stdio.h>

main()
{
  int a = 21; int b = 10; int c;
  if( a == b )
  {
    printf("Line 1 - a is equal to b\n");
  }
  else
  {
    printf("Line 1 - a is not equal to b\n");
  }
}
# Logical Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;&amp;</td>
<td>Called Logical AND operator. If both the operands are non-zero, then the condition becomes true.</td>
<td>(A &amp;&amp; B) is false.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>!</td>
<td>Called Logical NOT Operator. It is used to reverse the logical state of its operand. If a condition is</td>
<td>!(A &amp;&amp; B) is true.</td>
</tr>
</tbody>
</table>
#include <stdio.h>

main()
{
    int a = 5; int b = 20; int c;
    if ( a && b )
    {
        printf("Line 1 - Condition is true\n");
    }
    if ( a || b )
    {
        printf("Line 2 - Condition is true\n");
    }
/* lets change the value of a and b */
a = 0; b = 10;
if ( a && b )
{
    printf("Line 3 - Condition is true\n" );
}
else
{
    printf("Line 3 - Condition is not true\n" );
}
if ( !(a && b) )
{
    printf("Line 4 - Condition is true\n" );
}
## ASSIGNMENT OPERATORS

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Simple assignment operator. Assigns values from right side operands to left side operand</td>
<td>C = A + B will assign the value of A + B to C</td>
</tr>
<tr>
<td>+=</td>
<td>Add AND assignment operator. It adds the right operand to the left operand and assign the result to the left operand.</td>
<td>C += A is equivalent to C = C + A</td>
</tr>
<tr>
<td>-=</td>
<td>Subtract AND assignment operator. It subtracts the right operand from the left operand and assigns the result to the left operand.</td>
<td>C -= A is equivalent to C = C - A</td>
</tr>
<tr>
<td>*=</td>
<td>Multiply AND assignment operator. It multiplies the right operand with the left operand and assigns the result to the left operand.</td>
<td>C *= A is equivalent to C = C * A</td>
</tr>
<tr>
<td>/=</td>
<td>Divide AND assignment operator. It divides the left operand with the right operand and assigns the result to the left operand.</td>
<td>C /= A is equivalent to C = C / A</td>
</tr>
<tr>
<td>%=</td>
<td>Modulus AND assignment operator. It takes modulus using two operands and assigns the result to the left operand.</td>
<td>C %= A is equivalent to C = C % A</td>
</tr>
<tr>
<td>&lt;&lt;=</td>
<td>Left shift AND assignment operator.</td>
<td>C &lt;&lt;= 2 is same as C = C &lt;&lt; 2</td>

</tbody>
</table>
```c
#include <stdio.h>

main()
{
    int a = 21; int c;
    c = a;
    printf("Line 1 - = Operator Example, Value of c = %d\n", c);
    c += a;
    printf("Line 2 - += Operator Example, Value of c = %d\n", c);
    c -= a;
    printf("Line 3 - -= Operator Example, Value of c = %d\n", c);
    c *= a;
    printf("Line 4 - *= Operator Example, Value of c = %d\n", c);
}
```
• c = 200; c %= a;
• printf("Line 6 - %= Operator Example, Value of c = %d\n", c );
• c <<= 2;
• printf("Line 7 - <<= Operator Example, Value of c = %d\n", c );
• c >>= 2;
• printf("Line 8 - >>= Operator Example, Value of c = %d\n", c );
• c &= 2;
• printf("Line 9 - &= Operator Example, Value of c = %d\n", c );
• c ^= 2;
• printf("Line 10 - ^= Operator Example, Value of c = %d\n", c );
• c |= 2;
• printf("Line 11 - |= Operator Example, Value of c = %d\n", c );
• }
CONDITIONAL OR TERNARY OPERATORS IN C

• Conditional operators return one value if condition is true and returns another value is condition is false.
• This operator is also called as ternary operator.
• Syntax : (Condition? true_value: false_value);
• Example : (A > 100 ? 0 : 1);
```c
#include <stdio.h>

int main()
{
    int x=1, y;
    y = ( x ==1 ? 2 : 0 ) ;
    printf("x value is %d\n", x);
    printf("y value is %d", y);
}
```

Compiled by Ms. Prajakta Joshi
```c
#include<stdio.h>

int main()
{
    int age;

    printf(" Please Enter your age here: \n ");
    scanf(" %d ", &age);

    (age >= 18) ? printf(" You are eligible to Vote ") :
            printf(" You are not eligible to Vote ");

    return 0;
}
```
TYPE CONVERSION/TYPe CASTING

• Implicit Type Conversion/ Casting
• Explicit Type Conversion/ Casting
Implicit type casting means conversion of data types without losing its original meaning.

This type of typecasting is essential when you want to change data types without changing the significance of the values stored inside the variable.

Implicit type conversion happens automatically when a value is copied to its compatible data type.

During conversion, strict rules for type conversion are applied.

If the operands are of two different data types, then an operand having lower data type is automatically converted into a higher data type.
```c
#include<stdio.h>
int main()
{
    short a=10; //initializing variable of short data type
    int b; //declaring int variable
    b=a; //implicit type casting
    printf("%d\n",a);
    printf("%d\n",b);
}
```
EXAMPLE OF ITC FROM CHAR TO INT

#include<stdio.h>
int main()
{
  int x = 10;    // integer x
  char y = 'a';  // character c

  // y implicitly converted to int. ASCII
  // value of 'a' is 97
  x = x + y;

  // x is implicitly converted to float
  float z = x + 1.0;

  printf("x = %d, z = %f", x, z);
  return 0;
}

Compiled by Ms. Prajakta Joshi
EXPLICIT TYPE CONVERSION

- When interpretation is between a variable having a data type with respect to size & type both, this conversion is not possible for compiler automatically.
- It is performed by the programmer.
- In this type casting programmer tells compiler to type cast one data type to another data type using type casting operator.
- but there is some risk of information loss is there, so one needs to be careful while doing it.
C PROGRAM TO DEMONSTRATE
EXPLICIT TYPE CASTING

• #include<stdio.h>

• int main()
• {
  double x = 1.2;

  // Explicit conversion from double to int
  int sum = (int)x + 1;

  printf("sum = %d", sum);

  return 0;
  
}
C PROGRAM TO DEMONSTRATE EXPLICIT TYPE CASTING

• #include<stdio.h>
• int main()
• {
  •   float a = 1.2;
  •   //int b = a; //Compiler will throw an error for this
  •   int b = (int)a + 1;
  •   printf("Value of a is %f\n", a);
  •   printf("Value of b is %d\n",b);
  •   return 0;
• }

INPUT & OUTPUT FUNCTIONS

Console Input/Output functions

Formatted functions

<table>
<thead>
<tr>
<th>Type</th>
<th>Input</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>char</td>
<td>scanf()</td>
<td>printf()</td>
</tr>
<tr>
<td>int</td>
<td>scanf()</td>
<td>printf()</td>
</tr>
<tr>
<td>float</td>
<td>scanf()</td>
<td>printf()</td>
</tr>
<tr>
<td>string</td>
<td>scanf()</td>
<td>printf()</td>
</tr>
</tbody>
</table>

Unformatted functions

<table>
<thead>
<tr>
<th>Type</th>
<th>Input</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>char</td>
<td>getch()</td>
<td>putch()</td>
</tr>
<tr>
<td>int</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>float</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>string</td>
<td>gets()</td>
<td>puts()</td>
</tr>
</tbody>
</table>
GETCH() FUNCTION

- The getch() function reads the alphanumerical character input from the user. But, that the entered character will not be displayed.

```c
#include <stdio.h>
#include <conio.h>

int main() {
    printf("\nHello, press any alphanumerical character to exit ");
    getch();
    return 0; }
```

Compiled by Ms. Prajakta Joshi
GETCHE() FUNCTION

• getche() function reads the alphanumeric character from the user input. Here, character you entered will be echoed to the user until he/she presses any key.

```c
#include <stdio.h> //header file section
#include <conio.h>
int main() {
    printf("\nHello, press any alphanumeric character or symbol to exit \n ");
    getche();
    return 0; }
```

Compiled by Ms. Prajakta Joshi
GETCHAR() FUNCTION

• The getchar() function reads character type data form the input.
• The getchar() function reads one character at a time till the user presses the enter key.
#include <stdio.h> //header file section #include <conio.h>

int main()
{
    char c;
    printf("Enter a character : ");
    c = getchar();
    printf("\nEntered character : \%c ", c);
    return 0;
}
• The `gets()` function can read a full string even blank spaces presents in a string.
• But, the `scanf()` function leave a string after blank space space is detected.
• The `gets()` function is used to get any string from the user.
GETS() FUNCTION

#include <stdio.h>
#include <conio.h>
int main()
{
    char c[25];
    printf("Enter a string : ");
    gets(c);
    gets(c);
    printf("\n%s is awesome ",c);
    return 0;
}
PUTCH() FUNCTION

- The putch() function prints any alphanumerical character.

```c
#include <stdio.h> //header file section
#include <conio.h>

int main() {
    char c;
    printf("Press any key to continue\n");
    c = getch();
    printf("input : ");
    putch(c);
    return 0; }
```
Compiled by Ms. Prajakta Joshi
PUTCHAR() FUNCTION

- putchar() function prints only one character at a time.

```c
#include <stdio.h> //header file section #include <conio.h>
int main() {
    char c = 'K';
    putchar(c);
    return 0;
}
```

Compiled by Ms. Prajakta Joshi
PUTS() FUNCTION

• The puts() function prints the character array or string on the console. The puts() function is similar to printf() function, but we cannot print other than characters using puts() function.
#include <stdio.h>
#include <conio.h>

int main()
{
    char c[25];
    printf("Enter your Name : ");
    gets(c);
    puts(c);
    puts(c);
    return 0;
}
